

***RAW Office Building Communications
Network***

Computer Networks Project

by

Abizer Masavi E034

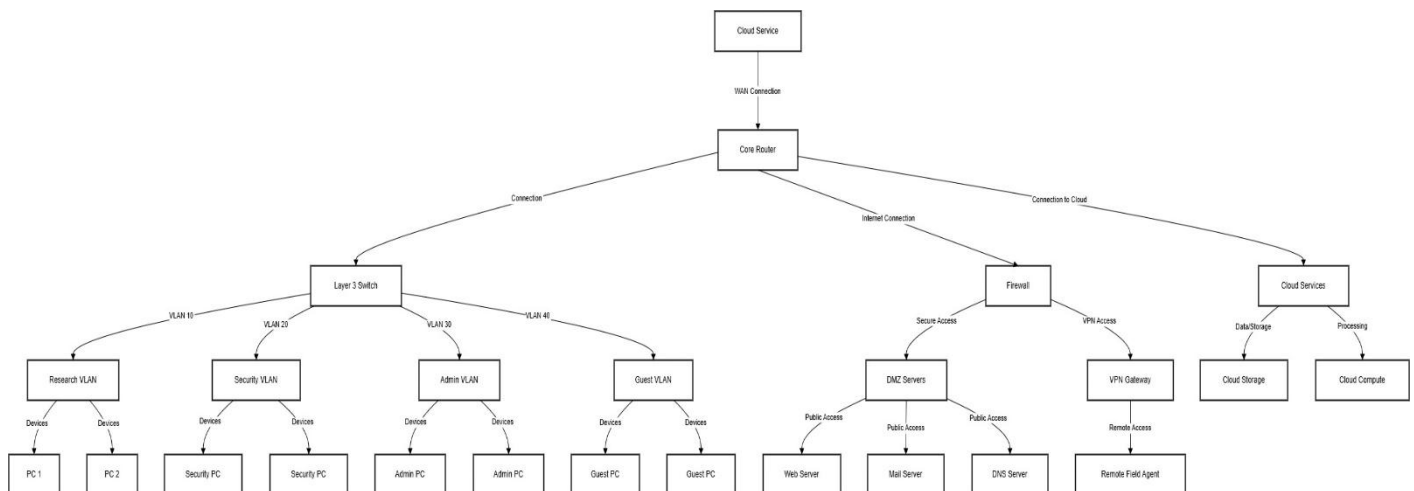

Subham Mohapatra E037

Arzaan Mulla E039

Introduction

The Research and Analysis Wing (RAW) network architecture is designed to provide a secure, scalable, and efficient infrastructure that supports the agency's critical intelligence operations. This network integrates advanced cloud-based services, VLAN segmentation, and robust security measures to safeguard sensitive data and ensure secure communication across departments and remote agents. The architecture includes firewalls, VPNs, and IDS/IPS systems to protect both internal and external communications, while enabling seamless access to resources for field agents. The network is designed for high availability and redundancy, ensuring that RAW can continue its operations without compromising security or performance.

The goal is to design a network system that supports efficient file sharing, communication tools, and access to shared resources, while considering factors like the physical layout, transmission medium, and network protocols. The proposed solutions will cover everything from network types and configurations to the choice of transmission media, IP addressing schemes, and security protocols.

Architecture for RAW office network

2. Requirements of the Case/Scenario

For the RAW office building, the following requirements are essential:

- **Departmental Communication:** Each department needs access to shared resources such as printers, files, and applications.
- **Internet Connectivity:** Employees must have access to the internet while maintaining a secure internal network.
- **Wireless Access:** The building must support wireless communication for mobile devices and laptops.
- **Server Access:** Critical services like DNS, DHCP, and file servers should be centralized to provide consistent and secure access.
- **VLAN Segmentation:** Different departments need to be separated using VLANs for network management, security, and performance optimization.
- **Scalability:** The network should be scalable to accommodate future growth, including adding more devices and departments without disrupting existing services.
- **High Availability:** Redundant paths for critical communications like servers and routers to ensure the network remains operational even if parts of it fail.

3. Types of Network Configuration Required

- **Client-Server Network Configuration:** This is the primary configuration for most of the office departments. Centralized servers will manage critical services such as file storage, printer access, DNS, and DHCP. End devices such as PCs, printers, and mobile devices will act as clients accessing these services.
- **Peer-to-Peer Configuration:** In specific areas such as smaller departments or isolated networks (e.g., IT team), peer-to-peer communication may be used for smaller-scale file sharing or direct device communication.
- **Hybrid Configuration:** In this case, the mix of client-server for departments needing centralized control (like HR, Finance, and IT) and peer-to-peer for smaller, independent groups (like the admin department) is ideal. The hybrid configuration ensures that departments with different communication needs have their appropriate setups, providing flexibility and scalability.

4. Types of Networks and Size of Networks

- **LAN (Local Area Network):** The office building fits within the LAN category, as all devices are confined within a single building or limited geographical area. The LAN will support a variety of communication protocols, high-speed data transfer, and offer centralized management.
- **VLAN Segmentation:** Since different departments (Sales, IT, Public Relations, Admin, etc.) require different network configurations, VLANs are used to segment traffic for security, performance, and ease of management. Each VLAN will have its own dedicated subnet.
- **IP Class:** The office network will use **Private IP Addressing (Class C - 192.168.x.x range)**, as the internal network does not need to be publicly routable. This ensures that there are enough IP addresses for all devices while also maintaining internal security.

Topologies with Justification

- **Star Topology for Office and Non-Critical Departments:** The star topology is ideal for RAW's general office network. In this setup, all devices, including PCs, workstations, and laptops, are connected to a central switch or router. This centralized approach simplifies network management and makes troubleshooting easier. Additionally, it allows for easy scalability as the network grows. If a single device or connection fails, it does not affect the rest of the network, which is crucial for maintaining operational continuity. Moreover, the centralized monitoring and security systems allow RAW's IT team to efficiently enforce security policies, track activity, and respond to threats in real-time.
- **Mesh Topology for Critical Systems:** A mesh topology is suitable for highly secure departments or critical network components within the RAW network, such as the server room and data storage systems. In a mesh network, each device has a direct connection to every other device, ensuring redundancy and reliable communication. This setup provides multiple paths for data to travel, reducing the risk of downtime and improving resilience. Mesh topology is particularly useful in high-traffic areas like the research network, where constant uptime is essential to process and store classified intelligence.
- **Hybrid Topology for Flexibility and Efficiency:** A hybrid topology is the most suitable for RAW, as it combines both star and mesh topologies to meet specific needs. For instance, critical departments like the security operations center or research and analysis rooms could use a mesh topology to ensure redundancy and fault tolerance. On the other hand, non-critical departments like administration or HR could implement a star topology for simplicity, cost-effectiveness, and easy management. This hybrid approach ensures that RAW's

network is both secure and efficient, meeting the requirements of both low and high-priority systems without unnecessary complexity.

6. Transmission Medium and Cost Considerations

- **Ethernet (Copper Cabling):** The most cost-effective and common solution for internal communications, using **Cat5e** or **Cat6** cables. These cables offer speeds up to 1 Gbps, which is sufficient for most office tasks such as file sharing, printing, and internet access. Ethernet also has lower installation costs and is easier to maintain.
- **Fiber Optic Cables:** Used for inter-floor or inter-building connections if high-speed communication is necessary between floors or areas with large data traffic. Although more expensive than copper, fibre optics provide significantly higher bandwidth and are more future-proof.
- **Wireless (Wi-Fi):** Wireless connectivity is used in areas like meeting rooms, employee lounges, and conference areas. Access points (APs) are strategically placed to ensure sufficient coverage. Wireless communication offers flexibility but may have limitations in terms of speed and range compared to wired connections.

7. Tentative Options for Types of Nodes Used

- **End Nodes:** These include:
 - **PCs:** Desktop computers for employees in different departments.
 - **Printers:** Network printers accessible by all departments.
 - **Smartphones and IP Phones:** Devices used by employees for communication (smartphones for mobile access and IP phones for voice communication).
- **Intermediate Nodes:** These include:
 - **Switches:** Switches serve as central nodes that manage local area traffic between devices within the same VLAN.
 - **Routers:** Routers connect different VLANs and handle inter-network traffic. They also provide routing between the office network and external networks such as the internet.
 - **Wireless Access Points (WAPs):** These devices extend the wireless network to mobile devices, allowing them to connect to the office network.

- **DMZ Servers:**

- **DNS Servers:** These servers resolve domain names to IP addresses, ensuring that employees can access websites using domain names. And helps in mail setup.
 1. **External DNS Server** - Hosted in the DMZ, these servers resolve public domain names and interact with external clients and the internet. The firewall between the DMZ and the internal network ensures that the internal DNS is protected from external threats.
 2. **Internal DNS Server** - These are hosted within RAW's internal network and are not accessible directly from the public internet. They resolve internal domain names for internal resources such as file servers, internal applications, and email servers.
- **DHCP Server:** Automatically assigns IP addresses to devices connecting to the network.
- **Email Servers:** Provide centralized access to shared files and printers across the building.
- **Web server :** Provides internal and safe email servers through mail.com on the DNS server.

8. Suggested IP Class Range with Justification

Private IP Range: 192.168.x.x:

- **VLAN 10 (Counterintelligence Division):** 192.168.10.0/24
- **VLAN 20 (Cyber Surveillance Unit):** 192.168.20.0/24
- **VLAN 30 (Strategic Operations):** 192.168.30.0/24
- **VLAN 40 (Cryptanalysis Division):** 192.168.40.0/24
- **VLAN 50 (IT and Communications):** 192.168.50.0/25
- **VLAN 60 (Server Room):** 192.168.60.0/27
- **VLAN 70 (Wireless Network):** 192.168.70.0/22

These subnets allow for up to **254 devices** in each major department, with a smaller subnet for the **Server Room** and **Wireless Network** based on their specific needs. The IP ranges ensure that the network remains private and isolated from public networks while providing sufficient address space for each department.

9. Suggested Protocol Model

- **TCP/IP Protocol Suite:** The **TCP/IP** model is the most commonly used protocol suite for office networks, offering support for reliable data transmission, routing, and internet connectivity. The **Internet Protocol (IP)** and **Transmission Control Protocol (TCP)** provide the necessary mechanisms for communication across the network, while **UDP** can be used for applications requiring faster transmission with less overhead.
- **OSI Model:** The **OSI model** helps in visualizing the network's layers, with focus on:
 - **Layer 3 (Network Layer):** IP routing between VLANs.
 - **Layer 2 (Data Link Layer):** Ethernet switches managing data link frames and MAC addressing.
 - **Layer 7 (Application Layer):** Protocols such as HTTP, FTP, and DNS to facilitate application communication within the office network.
- **Routing Protocols:** The **OSPF (Open Shortest Path First)** protocol could be employed for routing between different VLANs and for redundancy purposes within the internal network.

10. Security Features for RAW Network

Given the sensitive nature of the work handled by the Research and Analysis Wing (RAW), security is the highest priority in the network design. The network must be secure, reliable, and able to handle classified data without compromising its confidentiality, integrity, or availability. The following security features are crucial for the RAW network:

10.1 Network Segmentation with VLANs

- **VLAN Segmentation:** The network should be segmented into Virtual Local Area Networks (VLANs), isolating different departments (e.g., research, security, admin, and guest networks) to prevent unauthorized access between them. Sensitive data should reside in its own VLAN, ensuring that only authorized users can access it.
- **Security Control:** Implementing Access Control Lists (ACLs) on switches and routers ensures that each VLAN has controlled access to specific resources, minimizing the attack surface by limiting traffic flow between departments.

10.2 Firewalls

- **Perimeter Firewalls:** RAW's network should be protected by next-generation firewalls (NGFWs) such as Cisco Firepower at the network perimeter. These firewalls will inspect both incoming and outgoing traffic, enforcing security policies and blocking unauthorized access.
- **Internal Firewalls:** For additional security, internal firewalls should be deployed between VLANs to ensure strict control over intra-network communication. These firewalls act as gatekeepers, preventing unauthorized access to sensitive internal resources.
- **Web Application Firewall (WAF):** A WAF should be implemented to protect web servers and applications from common threats such as SQL injection, cross-site scripting (XSS), and DDoS attacks.

10.3 Intrusion Detection and Prevention Systems (IDS/IPS)

- **IDS/IPS:** An effective Intrusion Detection System (IDS) and Intrusion Prevention System (IPS) are essential for detecting and blocking malicious activities within the network. Snort, Suricata, or Cisco Firepower can be used to monitor and analyze network traffic for suspicious patterns, including malware, exploits, and anomalous behavior.
- **Real-time Alerts:** The IDS/IPS will send real-time alerts to the security operations center (SOC) whenever an attack is detected, enabling rapid incident response.

10.4 Virtual Private Network (VPN) for Secure Remote Access

- **VPN Gateway:** Field agents and remote workers must securely connect to the network using a VPN (Virtual Private Network). A site-to-site VPN or client-based VPN (using IPsec or SSL/TLS) ensures that communications between remote devices and the internal network are encrypted and authenticated.
- **Multi-Factor Authentication (MFA):** To ensure secure access, MFA should be implemented for remote users, requiring more than just a password for access. This adds an additional layer of protection against unauthorized access.

10.5 Zero Trust Architecture (ZTA)

- **Zero Trust Model:** A Zero Trust Architecture (ZTA) must be implemented across the entire network. This means that no device, user, or system is inherently trusted, even if it is inside the network. Every request for access to network resources must be authenticated, authorized, and encrypted.
- **Identity and Access Management (IAM):** An effective IAM system should be used to verify the identity of users and devices before granting access to any resource. Roles and permissions should be tightly controlled, with least-privilege access enforced for all users.

10.6 Data Encryption

- **Data at Rest:** All sensitive data stored on the network, whether on servers, databases, or cloud storage, should be encrypted using strong algorithms such as AES-256. This ensures that even if unauthorized access occurs, the data remains unreadable.
- **Data in Transit:** To protect data being transmitted across the network, SSL/TLS encryption should be used for web applications, email, and other communications. The VPN connection for remote workers also ensures that data in transit is encrypted.
- **Disk Encryption:** Devices used by field agents and other employees, including laptops and mobile phones, should have full disk encryption (e.g., BitLocker or FileVault) to protect against data theft or loss.

10.7 Access Control and Monitoring

- **Role-Based Access Control (RBAC):** Users should be granted access based on their role within the organization. For example, administrative users may have broader access, while researchers may only have access to certain data sets. This ensures that sensitive information is only accessible by authorized personnel.
- **Physical Access Control:** Biometric authentication (e.g., fingerprint scanners or facial recognition) should be implemented for physical access to data centers, server rooms, and other secure areas. Badge-based entry systems can also be used to monitor and restrict physical access.
- **Continuous Monitoring and Logging:** Security Information and Event Management (SIEM) tools should be used to monitor all network activity and generate real-time alerts. Centralized logging of security events is essential for forensic analysis, incident response, and compliance with regulatory standards.

10.8 DNS Security and Protection

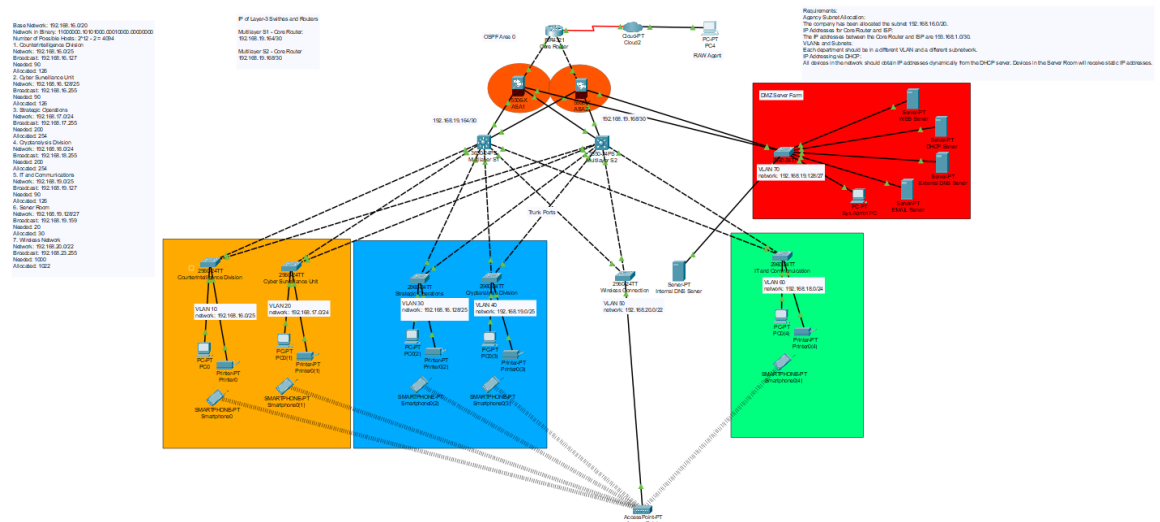

- **DNSSEC:** The use of DNS Security Extensions (DNSSEC) is crucial for protecting the network from DNS spoofing and cache poisoning attacks. By ensuring that DNS queries and responses are authentic and integrity-protected, RAW can prevent cybercriminals from redirecting users to malicious sites.
- **DNS Filtering:** Use DNS filtering to block access to known malicious websites and prevent users from accidentally visiting phishing sites or downloading malware.

10.9 Cloud Security and Compliance

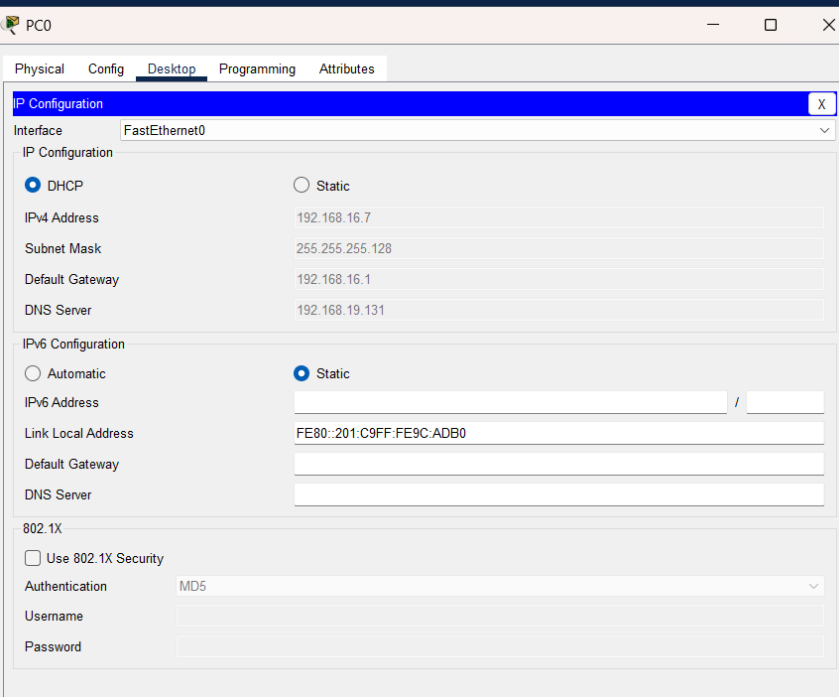

- **Cloud Access Security Broker (CASB):** RAW can use a CASB to monitor and enforce security policies for cloud-based services, ensuring that only authorized applications and services are used by employees. A CASB can also help with data loss prevention (DLP) and ensure compliance with security policies.
- **Cloud Data Encryption:** All cloud-based storage should be encrypted, and access should be controlled via IAM policies. Multi-factor authentication (MFA) should be required for accessing cloud resources to prevent unauthorized access.
- **Cloud Firewall:** Ensure that a cloud firewall is implemented to protect public-facing services in the DMZ and restrict access to critical resources within the internal network.

11. Screenshots and Visual Representation of the Network

1. **Screenshot 1:** Entire Network Map in Cisco Packet Tracer showing the connection between departments, switches, and routers.

2. Screenshot 2: PC0 IP configuration

The screenshot shows a network configuration window for PC0. The window has a title bar with 'PC0' and standard window controls. Below the title bar are tabs for 'Physical', 'Config', 'Desktop', 'Programming', and 'Attributes'. The 'Config' tab is active, and within it, the 'IP Configuration' sub-tab is selected. The 'Interface' dropdown is set to 'FastEthernet0'. The 'IP Configuration' section has two radio buttons: 'DHCP' (selected) and 'Static'. Below these are fields for 'IPv4 Address' (192.168.16.7), 'Subnet Mask' (255.255.255.128), 'Default Gateway' (192.168.16.1), and 'DNS Server' (192.168.19.131). The 'IPv6 Configuration' section has two radio buttons: 'Automatic' and 'Static' (selected). Below these are fields for 'IPv6 Address' (empty), 'Link Local Address' (FE80::201:C9FF:FE9C:ADB0), 'Default Gateway' (empty), and 'DNS Server' (empty). The '802.1X' section has a checkbox for 'Use 802.1X Security' (unchecked), a dropdown for 'Authentication' (MD5), and fields for 'Username' and 'Password' (both empty).

3. Screenshot 3: Router configurations for VLAN routing and DHCP server settings.

The screenshot displays the configuration interface for a Core Router. The interface is divided into several sections:

- Physical** tab: Shows the physical configuration of the interface.
- Config** tab: Shows the configuration settings for the interface.
- CLI** tab: Shows the CLI commands for the interface.
- Attributes** tab: Shows the attributes of the interface.

The **Config** tab is selected, showing the configuration for **GigabitEthernet0/0/0**. The configuration includes:

- Port Status**: ☒ On
- Bandwidth**: ☒ 1000 Mbps ☐ 100 Mbps ☐ 10 Mbps ☒ Auto
- Duplex**: ☐ Half Duplex ☒ Full Duplex ☒ Auto
- MAC Address**: 0060.5C02.A401
- IP Configuration**:
 - IPv4 Address**: 192.168.19.166
 - Subnet Mask**: 255.255.255.252
- Tx Ring Limit**: 10

Below the configuration settings, the **Equivalent IOS Commands** are listed:

```
Router(config-if)#exit
Router(config)#interface GigabitEthernet0/0/1
Router(config-if)#
Router(config-if)#exit

11. Firewall

In this network design, firewalls play a critical role in securing the internal network, the Demilitarized Zone (DMZ), and external sources like the internet. The configuration of the interfaces on the firewalls (ASA 5506-X devices) defines the trust levels for different network segments:

1. Internal Network (Gig1/1 and Gig1/2):

- **Gig1/1** is configured as an **internal trusted interface** with a **security level of 100**. This interface connects to the internal office network, providing access to internal systems like workstations, printers, and servers. Since the internal network is trusted, the firewall allows traffic to flow freely between this network and the DMZ, ensuring that no malicious traffic from the external network can affect it.
- **Gig1/2** is also configured as a **trusted interface** but assigned a **security level of 50**. This is the **DMZ network**, which contains services like web, email, and DNS servers that need to be accessible from both the internal network and the external internet. The DMZ is considered a semi-trusted zone because it needs to interact with external traffic but should still be separated from the core internal network for security reasons.

2. External Network (Gig1/4):

- **Gig1/4** is configured as an **external untrusted interface** with a **security level of 0**. This interface connects to the **internet** and is responsible for managing inbound and outbound traffic to/from external sources. The external network is not trusted, as it exposes the system to various threats and must be carefully controlled by the firewall.

Firewall Rules and Policies

• Access Control Lists (ACLs):

- ACLs should be applied to each interface to specify what kind of traffic is allowed to enter or exit from the network. For example, only HTTP/HTTPS traffic should be allowed to enter the DMZ servers from the external network (internet), while any traffic from the DMZ to the internal network should be restricted to the specific ports required for server management.

• NAT (Network Address Translation):

- The firewall should implement **NAT** to allow devices in the internal network and DMZ to share the public IP address for communication with external networks. This prevents internal IP addresses from being exposed to the outside world and adds an extra layer of security.

- **Inspection and Logging:**

- The firewall should inspect and log traffic passing through each interface. This includes looking for threats like port scanning, malware, and unauthorized access attempts. The logs should be regularly reviewed to identify and mitigate potential threats before they escalate.

How Real-World Companies Use Similar Firewalls at a Larger Scale

In larger organizations, the principles outlined in this setup are expanded into more complex configurations with multiple layers of security:

1. **Multiple Firewalls:**

- Large enterprises often use **multiple firewalls** placed in various strategic locations. For example, **Next-Generation Firewalls (NGFWs)** may be deployed at the perimeter, between internal segments, and even within individual departments for micro-segmentation.
- Firewalls in enterprise environments are not limited to protecting the perimeter but are also used to create isolated network zones like DMZs, dedicated user segments, and cloud environments.

2. **Distributed Denial of Service (DDoS) Protection:**

- Larger organizations typically integrate **DDoS protection** into their firewall systems. This involves automatically detecting and mitigating DDoS attacks before they can impact the services. For instance, companies like **Akamai** and **Cloudflare** provide DDoS mitigation services to ensure network traffic is not disrupted.

3. **Zero Trust Architecture:**

- Many modern enterprises now implement **Zero Trust Architecture (ZTA)**, where firewalls are part of a broader strategy to never trust any device or user inside or outside the network by default. Every access request is continuously validated using **identity-based security policies, multi-factor authentication, and micro-segmentation**. This approach is becoming critical as organizations adopt cloud and hybrid infrastructures.

4. **Example: Amazon Web Services (AWS)**

- In the cloud, organizations like **Amazon** use firewalls in the form of **AWS Security Groups** and **Network Access Control Lists (NACLs)** to create secure isolated environments for different services. They deploy multiple security layers around their cloud instances (VMs), databases, and storage to protect them from unauthorized access.

5. Example: Large Corporations (e.g., IBM, Cisco)

- Companies like **IBM** and **Cisco** often deploy **Firewalls in High Availability (HA) mode** to ensure continuous availability. They use **redundant** firewall configurations to prevent single points of failure, guaranteeing that if one firewall goes down, another automatically takes over.
- They also utilize **firewalls with Intrusion Prevention Systems (IPS)** to monitor network traffic for signs of suspicious activity and automatically block potentially harmful traffic.

By implementing multiple layers of security, firewalls not only prevent unauthorized access but also ensure that even if one security layer is bypassed, others will still protect critical infrastructure.

Conclusion

In conclusion, the network design for the RAW office building is engineered to meet the specific requirements of departmental communication, security, scalability, and high availability. By adopting a Client-Server network configuration for centralized control, alongside VLAN segmentation, we have successfully optimized the performance, security, and manageability of the network. The inclusion of Ethernet as the primary transmission medium, combined with fibre optics for high-bandwidth inter-floor connections, ensures efficient and cost-effective communication throughout the office.

The configuration of firewalls plays a pivotal role in securing both internal resources and external communications, with different security levels applied across various segments of the network, including the DMZ, internal network, and external interface. Network Address Translation (NAT) and Access Control Lists (ACLs) are implemented to prevent unauthorized access and manage traffic flow between different network zones.

The high availability design with redundant network paths and the strategic placement of firewalls ensures that the network remains resilient against failures and security threats, providing continuous service for all departments. The network is also designed with scalability in mind, allowing for seamless growth as new departments or devices are added without compromising performance or security.

In a larger enterprise context, similar strategies are applied but at a more complex scale. Companies implement multi-layered firewall solutions, integrating advanced features like Intrusion Prevention Systems (IPS), DDoS protection, and Zero Trust Architecture (ZTA) to ensure robust security across their networks. This multi-layered approach ensures that even if one security measure is bypassed, others provide continued protection. Furthermore, organizations such as Amazon and IBM deploy high availability firewall setups to ensure no downtime, with automated failovers to keep the network running smoothly.

Ultimately, this proposed network design for the RAW office building aligns with modern network requirements, balancing performance, security, and future scalability, while offering a flexible foundation that can be adapted to larger, more complex environments.
